Assistant Professor, Dept. of EEE, Bharath University, Chennai, Tamil Nadu, India

ABSTRACT: The multilevel inverter topology gives the advantages of usage in high power and high voltage application with reduced harmonic distortion without a transformer. This paper presents a comparative study of nine level diode clamped inverter for constant Switching frequency of sinusoidal Pulse width Modulation and sinusoidal Natural Pulse width Modulation with switching frequency.

I. INTRODUCTION

MULTILEVEL Pulse Width Modulation (PWM) in-verters have been gained importance in high per-formance power applications without requiring high ratings on individual devices, as static var compen-sators, drives and active power filters. A multilevel inver-ter divides the dc rail directly or indirectly, so that the output of the leg can be more than two discrete levels. As both amplitude modulation and pulse width modulation are used in this, the quality of the output waveform gets improved with low distortion. The advantages of multi-level inverter are good power quality, low switching losses, reduced output dv/dt and high voltage capability. Increasing the number of voltage levels in the inverter increases the power rating. The three main topologies of multilevel inverters are the Diode clamped inverter, Fly-ing capacitor inverter, and the Cascaded H-bridge inver-ter [1][2]. The PWM schemes of multilevel inverters are classified in to two types the multicarrier sub-harmonic PWM (MC-SHPWM) and the Multicarrier switching fre-quency optimal pulse width modulation (MC-SFOPWM) [4][5]. The MC-SHPWM diode clamped multilevel inver-ter strategy reduced total harmonic distortion and the MC-SFOPWM technique for multilevel inverter strategy enhances the fundamental output voltage [6]. This paper considered the most popular structure among the trans-formerless voltage source multilevel inverters, the diode-clamped converter based on the neutral point converter proposed by Akagea et al [1].

III. DIODE CLAMPED MULTILEVEL INVERTER

For an N level (between the phase and the negative rail) diode clamped inverter,
The number of levels in the line-to-line voltage waveform
will be k=2N-1 (1)
The number of levels in the line to load neutral of a star or
wye load will be p=2k-1 (2)
The number of capacitors required, independent of the
number of phase, is N_{cap}=N-1 (3)
While the number of clamping diodes per phase is
D_{clamp}=2(N-1) (4)
nstates=Nphases (5)
and the number of switches in each
leg is
Sn=2(N-1) (6)

The number of possible switch states is

IV. PWM METHODS FOR MULTILEVEL INVERTERS

The two basic approaches used to generate the PWM sig-nals for multilevel inverters are Sub harmonic or Sub-Oscillation carrier based PWM-modulating waveform comparison with offset triangular carriers Space Vector PWM-space vector modulation based on a rotating vector in multilevel space and these are the extensions of traditional two level con-trol strategies to several levels.

The two main advantages of PWM inverters in compari-son to square-wave inverters are (i) control over output voltage magnitude (ii) reduction in magnitudes of un-wanted harmonic voltages. Good quality output voltage in SPWM requires the modulation index (m) to be less than or equal to 1.0. For m>1 (over-modulation), the fun-damental voltage magnitude increases but at the cost of decreased quality of output waveform. The maximum fundamental voltage that the SPWM inverter can output (without resorting to over-modulation) is only 78.5% of the fundamental voltage output by square-wave inverter. In this paper one more PWM techniques have been consi-dered. The merits and demerits of these two PWM tech-niques are compared under comparable circuit conditions on the basis of factors like (i) quality of output voltage (ii) obtainable magnitude of output voltage (iii) ease of con-trol etc. The peak obtainable output voltage from the giv-en input dc voltage is one important figure of merit for the inverter.[9]

Carrara considered different methods of disposing the many carrier bands required in multilevel PWM.[10]
Four alternative carrier PWM strategies with differing phase relationships for a multilevel inverter [15] are as follows:

1) In-phase disposition (IPD), where all the carriers are in phase- Technique A1;
2) Phase opposition disposition (POD), where the carri-ers above the zero reference are in phase, but shifted by 180^0

ISSN (Print) : 2320 – 3765
ISSN (Online): 2278 – 8875

International Journal of Advanced Research in Electrical, Electronics and Instrumentation Engineering

(An ISO 3297: 2007 Certified Organization)

Vol. 4, Issue 2, February 2015

from those carriers below the zero reference-Technique A2;
3) Alternative phase opposition disposition (APOD), where each carrier band is shifted by 180^0 from the ad-jacent bands- Technique A3;
4) Phase Disposition (PD), all the carriers are phase shifted by 2 /(N-1) radians- Technique B.

PD strategy is used most frequently because it pro-duces minimum harmonic distortion for the line–to–line output voltage [13],[14],[15],[16],[17].

4.1 SubHarmonic Pulse Width Modulation SHPWM Technique

In SHPWM technique the intersection of the triangular carrier and the modulation wave determines the genera-tion of the pulse. This requires a carrier of much higher frequency than the modulation frequency. [6-8]The generated rectilinear output voltage pulses are modulated such that their duration is proportional to the instantaneous value of the sinusoidal waveform at the centre of the pulse; that is, the pulse area is proportional to the corresponding value of the modulating sine wave.[10-11]
If the carrier frequency is very high, an averaging effect occurs, resulting in a sinusoidal fundamental output with high-frequency harmonics, but minimal low-frequency harmonics.

4.2 Switching Frequency Optimal Pulse width Modulation SFOPWM Technique

Steinke [12] proposed SFOPWM, a carrier based method where addition of triplen harmonic to the fundamental frequency Sinusoidal lowers the peak magnitude, thus allowing operating in over modulation region. This in-creases the inverter output voltage without compromis-ing on the quality of the output waveform [3][4].
Equations (9) to (12) are used to obtain the modulating wave.

$$V_{offset} = (\max(V_a,V_b,V_c) + \min(V_a,V_b,V_c))/2 \quad (9)$$
$$VaSFO = Va - Voffset \quad (10)$$
$$VbSFO = Vb - Voffset \quad (11)$$
$$VcSFO = Vc - Voffset \quad (12)$$

Where m is the number of carrier waves also the level of the inverter, required for pulse generation.

A sinusoidal and its modulated wave obtained from (13), (14) are shown in Fig.3 for a modulation index of 1.

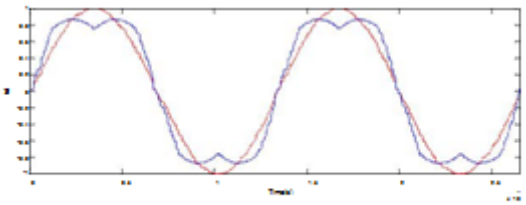

Figure 3 Single Phase Modulating Wave

4.3 Sinusoidal Natural PWM and Sinusoidal PWM Techniques

Operation of a multilevel inverter at low switching fre-quency is the Sinusoidal natural PWM and alternately sinusoidal PWM technique is operation at high switching frequency.

V. ANALYSIS OF NINE LEVEL DIODE CLAMPED INVERTER

A three-phase nine-level diode-clamped inverter is shown in Fig.4 [15][17]. Each phase is constituted by 16 switches (eight switches for upper leg and eight switches for lower leg). Switches S_{a1} through S_{a8} of upper leg form comple-mentary pair with the switches S_{a1} to S_{a8} lower leg of the same phase. The complementary switch pairs for phase 'A' are (S_{a1}, S_{a1}), (S_{a2}, S_{a2}), (S_{a3}, S_{a3}), (S_{a4}, S_{a4}), (S_{a5}, S_{a5}), (S_{a6}, S_{a6}), (S_{a7}, S_{a7}), (S_{a8}, S_{a8}) and similarly for B and C phases [1],[2],[3],[4],[5],[6],[7],[8],[17]. Clamping diodes are used to carry the full load current.

low-harmonic distortion waveform characteristics with well-defined harmonic spectrum, the fixed switching frequency, and implementation simplicity. Simple tech-niques for generating the modulation waves of the high-performance PWM methods are described. [19]The two novel methodologies Natural Sinusoidal PWM and Sinusoidal PWM for 3rd harmonic injected modulated wave called SFOPWM using constant switching frequency are compared[4],[5]. The one most important modulator charac-teristics—the total harmonic distortion is analytically modeled and compared for various carrier pwm methods applied to a nine level Neutral point clamped or Diode clamped inverter. Simulations of the controller and of the inverter have been made in the MATLAB SIMULINK environment.[18]

A nine level inverter is simulated for a normal modula-tion index of 0.8 and over modulation index of 1.1 at a switching frequency of 450Hz for Sinusoidal natural PWM and 1050Hz for Sinusoidal PWM technique.

VI. SIMULATION RESULTS AND DISCUSSIONS

Table 2 show at normal modulation index of 0.8 im-proved performance with reduced harmonic distortion is observed with SPWM technique for A1through B tech-niques for nine level diode clamped inverter.
